

Indiana Traffic Safety Facts 2001

County Alcohol Estimates

<http://www.in.gov/cji>

The following data provides estimates of alcohol involvement in fatal crashes in Indiana and individually for the 92 counties in the state. These estimates are based on data from NHTSA's Fatality Analysis Reporting System (FARS). Unfortunately, known blood alcohol content (BAC) test results are not available for all drivers and nonoccupants involved in fatal crashes. Missing data can result for a number of reasons, the most frequent being that the persons are not always tested for alcohol.

The terms and definitions used in the Indiana County Alcohol Estimates Fact Sheet have been extracted from the NHTSA State Alcohol Estimates Fact Sheet. This Fact Sheet is based upon the data contained in the officer's crash form and estimated values where critical data is missing. The following paragraphs are designed to better aid the reader in understanding the methodology and rationale for the resultant data.

"To address the missing data issue, NHTSA has developed and employs a statistical model to estimate the likelihood that a fatal crash-involved driver or nonoccupant was sober, had some alcohol, or was intoxicated at the time of the crash. The statistical model is based on important characteristics of the crash including crash factors (e.g., time of day, day of week, type of crash, location), vehicle factors (e.g., vehicle type and role in the crash), person factors (e.g., age, sex, restraint use, previous driving violations), and whether or not the state had a 21-year-old minimum drinking age law. The statistical model was developed using all available known data in the aggregate (that is, at the national level) and applied to each individual driver and nonoccupant with an unknown BAC test result. The estimates presented include a mix of both known and estimated BACs.

In 2001, NHTSA began using a revised method—**multiple imputation**—to estimate missing information about BAC levels for persons involved in fatal crashes. The alcohol estimates in this fact sheet are based on the new imputation method. The new method will improve the scope of alcohol involvement statistics generated from the Fatality Analysis Reporting System (FARS). NHTSA has also calculated historical estimates of alcohol involvement from 1982 through 2000 using the new method. Instead of estimating alcohol involvement in the three categories used in the past (0.00, 0.01 to 0.09, and 0.10+ grams per deciliter [g/dl]), the new method estimates BAC levels over the entire range of plausible values from 0.00 to 0.94 g/dl. As a result, NHTSA will have the ability to report alcohol involvement at any BAC level. Because many states, including Indiana, have adopted 0.08 g/dl as the legal threshold for alcohol intoxication, NHTSA now estimates alcohol involvement in the following three categories: 0.00 g/dl, no alcohol; 0.01 to 0.07 g/dl, impaired; and 0.08+, intoxicated. More information on the new multiple imputation method, including detailed tabulations of alcohol involvement in various categories (age, sex, time of day, etc.), is available in NHTSA Technical Report DOT HS 809 403, *Transitioning to Multiple Imputation: A New Method to Estimate Missing Blood Alcohol Concentration (BAC) Values in FARS*.

Great caution should be exercised in comparing the levels of alcohol involvement among counties. Differences in alcohol involvement can be due to any number of factors not necessarily directly related to alcohol traffic safety programs. Factors affecting alcohol involvement in fatal crashes include:

- Population demographics and the economic environment (older drivers and female drivers exhibit lower levels of alcohol involvement, drivers

of older vehicles exhibit higher levels of alcohol involvement, pedestrian fatalities as a group exhibit high levels of alcohol involvement);

- Degree of urbanization (alcohol involvement in single- and multi-vehicle crashes tends to be greater in urban fatal crashes, while alcohol involvement in nonoccupant fatal crashes is higher in rural areas);
- Types of vehicles (motorcycle drivers exhibit high levels of alcohol involvement followed by drivers of light trucks/vans; drivers of medium and heavy trucks exhibit the lowest levels of alcohol involvement)."

One of the major differences among counties is in the degree of testing for driver and nonoccupant BACs. These differences in testing affect the accuracy and reliability of the estimates presented.

Estimates of Alcohol-Involved Fatalities

The following tables estimate alcohol involvement for Indiana and on a county-by-county basis for 1994* and 2001 using NHTSA's multiple imputation model as applied to the FARS data. This model estimates BACs of drivers and nonoccupants when their BAC is not available. The displayed values represent the combination of known and estimated BACs. A fatality is considered *alcohol-related* if any driver or nonoccupant involved in the crash is tested or estimated to have a BAC of 0.01 or greater (the last column on the right in the tables). Estimates are presented for four categories:

- (1) BAC of 0.00
- (2) BAC of 0.01-0.07
- (3) BAC of 0.08 or greater
- (4) BAC of 0.01 or greater (the sum of (2) and (3)).

National versus Indiana Results

Nationwide in 2001, alcohol was involved in 41 percent of the traffic fatalities, or an estimated 17,448 alcohol-related fatalities. For the same year, alcohol was estimated to be involved in 37 percent (337 fatalities) for the State of Indiana. It is estimated that a BAC level of 0.08 or greater contributed to 31 percent of the fatalities (BAC level less than 0.08 contributed to 6 percent of the fatalities). This compares to the same national statistics of 35 percent and 6 percent, respectively.

For comparison purposes, base year results are included. The base year for the Indiana data is 1994, which represents the first year that imputed results are available at the county level.

* Data prior to 1994 is not available from the FARS query systems; thus 1994 and 2001 were used for this Indiana fact sheet.

Estimates of Drivers in Alcohol-Involved Fatal Crashes

The following tables estimate alcohol involvement for Indiana and on a county-by-county basis for 1994 and 2001 using NHTSA's discriminant function model as applied to the FARS data. This model estimates BACs of drivers when their BAC is not available. The displayed values represent the combination of known and estimated BACs. A fatal crash is considered *alcohol-related* if any involved driver is tested or estimated to have a BAC of 0.01 or greater (the last column on the right in the tables). Estimates are presented for four categories:

- (1) BAC of 0.00
- (2) BAC of 0.01-0.07
- (3) BAC of 0.08 or greater
- (4) BAC of 0.01 or greater (the sum of (2) and (3)).

National versus Indiana Results

Nationwide in 2001, alcohol was present in 26 percent of the drivers involved in fatal crashes (BAC 0.01-0.07, 4 percent; BAC 0.08 or greater, 21 percent).

Statewide in 2001, alcohol was present in 24 percent of the drivers involved in fatal crashes (BAC 0.01-0.07, 4 percent; BAC 0.08 or greater, 20 percent).

Availability of Known BAC Test Results

The following tables present the percentage of drivers and nonoccupants involved in fatal crashes where a BAC test was given and the results were in the FARS file. Individual tables are presented for all drivers/nonoccupants, fatally injured drivers and surviving drivers.

National versus Indiana Results

Nationwide in 2001, a total of 16,653 fatally injured drivers had BAC test results out of a total of 25,840, or 64 percent. For surviving drivers, BAC test results were known on 7,736 out of 31,640 drivers, or 24 percent. Overall in 2001, FARS contained BAC test results on a total of 24,389 drivers out of 57,480 involved in fatal crashes, or 42 percent. Statistics for the base year 1982 are also presented. Any individual state proportion greater than the national percentage is considered good. The higher the proportion of drivers with known BAC test results, the more reliable the state estimate.

Statewide in 2001, a total of 333 fatally injured drivers had BAC test results out of a total of 613, or 54 percent. This is 10 percent lower than the national results. For surviving drivers, BAC test results were known on a total of 388 out of 672 drivers, or 58 percent. This percentage is much higher than the national number of 24 percent.
